Dynamic Arrays

Κ08 Δομές Δεδομένων και Τεχνικές Προγραμματισμού
Κώστας Χατζηκοκολάκης
How can we implement ADTVector?

• A Vector can be seen as an abstract resizable “array”

• So it makes sense to **implement** it using a **real array**
  - store Vector's elements in the array
    - `vector_get_at`, `vector_set_at` are trivial

• But what about `vector_insert_last`?
  - Arrays in C have fixed size
Dynamic arrays

- Main idea: **resize** the array
  - such arrays are called “dynamic” or “growable”

- **Problem**: we need to **copy** the previous values

- A possible algorithm for **vector_insert_last**
  - Allocate memory for **size+1** elements
  - Copy the **size** previous elements
  - Set the new element as last
  - Increase **size**

- What is the complexity of this?
  - $O(n)$, because of the copy!
  - Can we do better?
Dynamic arrays

• Main idea: resize the array
  - such arrays are called “dynamic” or “growable”

• Problem: we need to copy the previous values

• A possible algorithm for vector_insert_last
  - Allocate memory for size+1 elements
  - Copy the size previous elements
  - Set the new element as last
  - Increase size

• What is the complexity of this?
  - $O(n)$, because of the copy!
  - Can we do better?
Improving the complexity of insert

• **Idea**: allocate more memory than we need!
  - eg. allocate memory for 100 “empty” elements
    - **capacity**: total allocated memory
    - **size**: number of inserted elements
  - Insert is $O(1)$ if we have free space (just copy the new value)

• Does this change the complexity?
  - in the **worst-case**?
  - in the **average-case**?

• **No**, for some values of $n$ the operation is still slow!
  - For any values, “average-case” makes no difference
Improving the complexity of insert

- **Idea**: allocate more memory than we need!
  - eg. allocate memory for 100 “empty” elements
    - capacity: total allocated memory
    - size: number of inserted elements
  - Insert is \( O(1) \) if we have free space (just copy the new value)

- Does this change the complexity?
  - in the worst-case?
  - in the average-case?

- **No**, for some values of \( n \) the operation is still slow!
  - For any values, “average-case” makes no difference
Amortized-time complexity

• We see here the value of **amortized-time** complexity
  - A single execution **can** be slow
  - But “most” are fast
  - In many application we only care about the **average** wrt all **executions**

• Assume we reserve 100 more elements each time
  - How many steps each insert takes on average?

• Intuitively: $\frac{n}{100}$. So **still** $O(n)$, same complexity!
  - Same for any **constant** number of empty elements $k$
  - Remember, complexity cares about large $n$! Think $n \gg k$
  - Can we do better?
Amortized-time complexity

- We see here the value of *amortized-time* complexity
  - A single execution can be slow
  - But “most” are fast
  - In many application we only care about the average wrt all executions

- Assume we reserve 100 more elements each time
  - How many steps each insert takes on average?

- Intuitively: \( \frac{n}{100} \). So still \( O(n) \), same complexity!
  - Same for any constant number of empty elements \( k \)
  - Remember, complexity cares about large \( n \)! Think \( n \gg k \)
  - Can we do better?
How to improve the complexity

- **Idea**: the number of empty elements must depend on $n$
  - Use more empty elements as the Vector grows!

- Standard approach: reserve $a \cdot n$ extra elements
  - for some constant $a > 1$, called the **growth factor**

- Common values
  - $a = 2$
  - $a = 1.5$

- In this class we will use $a = 2$
  - we always **double** the capacity
A property to remember

- Consider the geometric progression with ratio 2
  \[1, 2^1, 2^2, \ldots, 2^n\]

- Summing \(n\) terms, we get the next one minus 1
  \[1 + 2^1 + 2^2 + \ldots + 2^n = 2^{n+1} - 1\]

- So each term is larger than all the previous together!
  - This is important since several quantities double in data structures
From linear to constant time

- We always **double** the capacity
  - What is the amortized-time complexity of insert?

- We do \( n \) insertions starting from an empty Vector
  - Assume the last one was “slow” (the most “unlucky” case)

- How many **steps** did we perform **in total**?
  - \( n \) steps just for placing each element
  - \( n \) steps for the **last resize**
  - How many for **all the previous resizes together**?

\[
\frac{n}{2} + \frac{n}{4} + \ldots + 1 = n - 1
\]

- So less than \( 3n \) in total!
  - On average: \( \frac{3n}{n} = O(1) \)
- Key point: previous inserts are insignificant compared to the last one
Removing elements

- What about **vector_remove_last**?
- Simplest strategy: just consider the removed space as “empty”
  - **vector_remove_last** is clearly worst-case $O(1)$
  - Insert is not affected (we never reduce the amount of free space)
- Commonly used in practice
  - eg. **std::vector** in C++
- **Problem**: wasted space
Recovering wasted space

• **Idea**: if half of the array becomes empty, resize
  - the opposite of the doubling growing strategy
  - Is this ok?

• Careful
  - this is ok if we only remove
  - but a combination of remove+insert might become slow!

• Think of the following scenario
  - Insert $n$ elements with $n = 2^k$
  - The vector is now full
  - Perform a series of: insert, remove, insert, remove, …
Recovering wasted space

• **Idea**: if half of the array becomes empty, resize
  - the opposite of the doubling growing strategy
  - Is this ok?

• Careful
  - this is ok if we only remove
  - but a combination of remove+insert might become slow!

• Think of the following scenario
  - Insert $n$ elements with $n = 2^k$
  - The vector is now full
  - Perform a series of: insert, remove, insert, remove, …
Recovering wasted space

- **Better strategy**
  - when only $\frac{1}{4}$ of the array is full
  - resize to $\frac{1}{2}$ of the capacity!
  - So we still have “room” to both insert and remove

- We can show that even a combination of insert+remove is $O(1)$ amortized-time
Implementation

Types

```c
// Ένα VectorNode είναι pointer σε αυτό το struct.

struct vector_node {
    Pointer value;       // Η τιμή του κόμβου.
};

// Ένα Vector είναι pointer σε αυτό το struct

struct vector {
    VectorNode array;     // Τα δεδομένα, πίνακας από struct ve
    int size;             // Πόσα στοιχεία έχουμε προσθέσει
    int capacity;         // Πόσο χώρο έχουμε δεσμεύσει
    DestroyFunc destroy_value; // Συνάρτηση που καταστρέφει ένα στοι
};
```
Vector vector_create(int size, DestroyFunc destroy_value) {
    // Αρχικά το vector περιέχει size μη-αρχικοποιημένα στοιχεία, αλλά
    // δεσμεύουμε χώρο για τουλάχιστον VECTOR_MIN_CAPACITY για να απο
    // πολλαπλά resizes
    int capacity = size < VECTOR_MIN_CAPACITY ? VECTOR_MIN_CAPACITY :
                  size;
    // Δέσμευση μνήμης, για το struct και το array.
    Vector vec = malloc(sizeof(*vec));
    VectorNode array = calloc(capacity, sizeof(*array));   // αρχικοπο
    vec->size = size;
    vec->capacity = capacity;
    vec->array = array;
    vec->destroy_value = destroy_value;

    return vec;
}
Random access is simple, since we have a real array.

```c
Pointer vector_get_at(Vector vec, int pos) {
    return vec->array[pos].value;
}

void vector_set_at(Vector vec, int pos, Pointer value) {
    // Αν υπάρχει συνάρτηση destroy_value, την καλούμε για
    // το στοιχείο που αντικαθίσταται
    if (value != vec->array[pos].value && vec->destroy_value != NULL)
        vec->destroy_value(vec->array[pos].value);

    vec->array[pos].value = value;
}
```
Implementation

Insert, we just need to deal with resizes.

```c
void vector_insert_last(Vector vec, Pointer value) {
    // Μεγαλώνουμε τον πίνακα (αν χρειαστεί), ώστε να χωράει τουλάχιστον
    // στοιχεία. Διπλασιάζουμε κάθε φορά το capacity (σημαντικό για τη
    // πολυπλοκότητα!)
    if (vec->capacity == vec->size) {
        vec->capacity *= 2;
        vec->array = realloc(vec->array, vec->capacity * sizeof(*new_}
        
    // Μεγαλώνουμε τον πίνακα και προσθέτουμε το στοιχείο
    vec->array[vec->size].value = value;
    vec->size++;
}
```
Takeaways

- **Dynamic arrays** are the standard way to implement ADTVector

- Insert is $O(1)$
  - but **amortized-time**!
  - would you use a dynamic array in the software controlling an Airbus?

- Remove is also $O(1)$
  - also amortized, if we care about recovering wasted space

- Random access (get/set) is always worst-case $O(1)$
